

ORIGIN

Build **ORIGIN — From the First Spark to the Next Idea**, a cinematic storytelling website for a fictional creative technology studio.

Study the attached recordings for atmosphere, visual depth, camera movement, and interaction quality. Create an original design with the same immersive feel. Prioritize exceptional art direction, detailed environments, elegant typography, sophisticated transitions, and ambitious but carefully choreographed animations.

Assets and approval

Fish Audio MCP is already connected. Use it for all images, videos, and voiceovers.

- Images: **GPT Image 2.5**
- Videos: **Seedance 2.5**
- Narration: **Drama 3**

Verify these models and their capabilities are available; ask before substituting.

Generate the first and last frame of every video through Fish Audio. Show me each pair with its planned camera movement and wait for my approval before generating that video. Keep both frames visually consistent and use them as the actual starting and ending inputs when supported.

Build these five sections:

1. The First Spark — Opening video

A prehistoric woman in a rough hooded hide cloak walks toward the camera carrying a burning torch. Surround her with dark rocks, low fog, sparse embers, and faint blue backlighting. Begin wide and end closer, revealing her face in warm firelight. Natural walking, subtle cloak movement, and a mostly steady camera.

Play automatically after entering the website. No click-and-hold here.

Narration: “Before we built cities, before we gave our ideas a name, we carried a spark into the dark. A small light. An endless question. What could we create?”

2. The Age of Craft — Click and hold

A monumental ancient stone workshop with an unfinished sculpture, carved fragments, warm light shafts, and atmospheric dust.

Holding moves the camera smoothly around the sculpture in a broad 60–90-degree arc, revealing its unfinished side and the workshop behind it.

Narration: “We learned to shape what we imagined. Stone became expression. Tools became extensions of our hands. And an idea could finally stand before us.”

3. The Age of Invention — Click and hold

A historical workshop containing an intricate brass-and-iron invention, surrounded by tall windows, wooden tables, and engineering drawings.

Holding moves the camera from front-left to rear-right with a gentle rise, revealing the internal machinery. Mechanical motion should be minimal and slow.

Narration: “Then we asked our ideas to do more. To turn. To connect. To carry us further. Imagination became invention, and possibility began to move.”

4. The Age of Imagination — Scroll-controlled 3D gallery

Build this environment yourself using **Three.js/WebGL**, with Fish-generated artwork. Take inspiration from the reference’s gallery sequence, but create a more distinctive, elaborate experience.

Create a vast dark exhibition hall with reflective obsidian flooring, suspended arches, fog, layered architecture, and warm gold lighting transitioning into icy blue.

Show four original artworks:

- A stone giant carrying a miniature city.
- A mechanical bird with intricate brass wings.
- A floating botanical island.
- ORIGIN’s futuristic headquarters, matching section five.

Scrolling moves the camera along a sweeping route through the gallery. Use layered images for depth, surrounded by actual 3D geometry. Add rotating frames that align, unfolding architectural fins, traveling floor lights, particles tracing silhouettes, and refined text reveals. Stage one major reveal at a time.

Pin the section during the journey and support reverse scrolling. End by expanding the headquarters artwork into section five.

Narration: “What once lived only in the mind can now become a world. A character. A place no one has seen before. We create experiences people can step into—and remember.”

5. ORIGIN Headquarters — Click and hold to enter

A striking contemporary headquarters combining sculptural stone, metal, glass, warm interior light, and reflective water.

Holding moves the camera smoothly from outside, through an open entrance, into the main atrium. Reveal live website content inside: About, Services, Selected Projects, and a “Start a project” CTA.

Narration: “That same spark still drives us. At ORIGIN, we turn curiosity into identities, spaces, and digital experiences. Every project begins with a question. What could we create together?”

Motion and interactions

Scrolling transitions between sections; holding explores sections 2, 3, and 5. Release pauses the video at its current position; hold again resumes. Include a subtle hold-progress cursor, replay, and touch/keyboard support.

Video scenes must be continuous shots of consistent environments, with noticeable but smooth camera movement. Apart from the opening woman, keep subject motion restrained. No cuts, morphing objects, excessive effects, or text baked into videos. Add typography and interface elements in code.

Connect chapters using fog, darkness, matched lighting, and architectural transitions. Use charcoal, midnight blue, amber, realistic materials, subtle bloom, and strong cinematic depth.

Loading and audio

Create a **procedural Three.js/WebGL loader, never a video**: embers gather into an abstract spark symbol and reveal ORIGIN, then dissolve into the opening. Tie progress to real loading and include “Enter experience” with a sound choice.

Generate a consistent mature female storytelling voice: warm, intimate, calm, and cinematic. Use separate chapter recordings, captions, mute, and replay controls. Keep narration independent of hold-release pauses and prevent overlapping audio.

Build the complete responsive website with polished navigation, smooth playback, progressive asset loading, reduced-motion support, and a consistently visible cursor. Test all transitions and interactions. Implement the site while awaiting frame approval, then integrate the approved videos and finish the experience.

Do you like this personality?

Enhance our existing ORIGIN website

Enhance our existing ORIGIN website with the changes below. Keep the current five-section concept and generated assets, and refine the experience rather than rebuilding it.

1. Add a cinematic story timeline and interface details

Create a persistent horizontal timeline near the bottom of the screen: a fine ruler-like line with small ticks, larger chapter markers, compact uppercase labels, and a softly glowing progress indicator.

Use these chapters: **First Spark** → **Craft** → **Invention** → **Imagination** → **ORIGIN**. Highlight the active chapter and animate the indicator smoothly between chapters. Make the markers clickable, using the same transitions as scrolling.

Add subtle framing details: small corner brackets, delicate side ticks, chapter numbering, and refined interaction hints. Keep everything restrained and leave the central visuals clear. Position captions above the timeline so they never overlap.

2. One deliberate scroll per transition

One clear mouse-wheel or trackpad gesture should move exactly one section forward or backward. Ignore tiny accidental movements and prevent momentum from skipping multiple sections. Lock navigation during transitions and require a fresh gesture afterward.

Preserve the internal scroll journey in the Age of Imagination gallery. At its beginning or end, one deliberate outward scroll should transition to the adjacent section.

Make transitions more noticeable and cinematic: combine a smooth camera-like push, atmospheric fog or shadow sweep, and staggered text reveals. Aim for roughly one second, with no black flashes or abrupt jumps.

3. Smooth voiceover transitions

When leaving a section, fade its narration out over approximately 400–600 milliseconds, then stop it. Fade the next narration in as the new section settles. Never overlap spoken sentences or delay navigation until narration finishes.

Keep **Heisty's Voice** for all storytelling narration. Preserve the current recordings where possible.

4. Faster hold playback and reverse on release

Make the hold-controlled videos play **twice as fast as their current playback speed**.

For sections two and three:

- Hold the left mouse button to play forward.
- Release to smoothly reverse from the current position back to the first frame.
- Use the same increased speed for the return.
- If the user holds again during reversal, resume forward from the current position without jumping.
- Once back at the beginning, remain there until held again.

For the final headquarters section:

- Hold to advance at the increased speed.
- Releasing pauses at the current position; it must not reverse.
- When the user scrolls back toward section four, first reverse the headquarters video to its opening frame at **3× normal speed**, then transition to section four automatically. This must require only that one scroll gesture.
- Fade out the interior company details as the reverse begins.

Implement reliable, smooth reverse playback using an appropriate technique, such as locally prepared reverse clips with matching timestamps. Do not rely on unsupported negative playback rates. Reuse the existing videos.

5. Clear the Age of Imagination gallery

Remove the large dark vertical fins, opaque foreground slabs, and oversized structural elements that cross the middle of the view and obscure the artwork or text. These currently look like black shutters between the camera and the exhibits.

Keep the environment's depth, illuminated artwork frames, and attractive thin orbiting accents, but move surrounding architecture away from the main viewing path. Ensure the artwork and descriptions remain clearly visible throughout the camera movement.

Reduce the orbit animation to **two or three slow revolutions across the entire gallery journey**, rather than repeated rapid spinning. Tie rotation to overall gallery progress, with gentle easing and no accumulated extra rotations from repeated scroll events.

6. Add sound effects and quiet background music

Use the connected **Fish Audio MCP** to generate suitable sound effects and background music. First check which tools support these capabilities; if either is unavailable, explain the limitation before substituting another source.

Create restrained sounds for:

- Chapter transitions: soft cinematic whooshes.
- Important button and timeline hovers: quiet, delicate ticks.
- Hold activation: a subtle rising atmospheric tone.

- Release and reverse: a gentle descending or reverse sweep.
- Headquarters arrival: a soft resonant finish.

Trigger sounds on interaction changes, not continuously on every frame. Prevent rapid hovering or clicking from stacking sounds.

For background music, create a seamless, calm but slightly eerie cinematic ambience: deep soft drones, airy textures, sparse distant notes, and a faint wordless low vocal layer. No lyrics, jump scares, heavy percussion, or competing spoken voice.

Play the music quietly across chapters without restarting it at every transition. Lower its volume further during narration. Respect the sound toggle and browser audio-unlock requirements.

7. Add subtle rising fireflies

Add a lightweight procedural particle layer across all five sections, excluding the loading screen.

Small glowing particles should emerge from the bottom of the viewport and drift upward with gentle sideways movement. Use mostly muted amber, warm ivory, and occasional pale blue. Vary their size, depth, speed, and glow subtly.

Keep the density low, the center readable, and the effect atmospheric. Particles should fade in and out naturally, never block interactions, and remain visually continuous between chapters.

Test scroll navigation, interrupted hold/reverse actions, the final-section exception, narration fades, audio mixing, gallery visibility, and mobile performance. Complete the changes in the existing project.

Woman’s GLB file

Update the first scene using the woman’s **GLB file in the project folder**.

Video-to-3D reveal: When the opening video finishes, replace it with a static background and reveal the 3D woman through a glowing scanning animation with

subtle embers. Use **Fish Audio** to create the background from the final frame, removing the woman and torch while preserving the environment. Match the model's pose, position, scale, lighting, and camera angle to the video. Preload everything for a seamless transition.

Natural movement and cursor following: Add gentle breathing, occasional blinking, and subtle posture shifts. Her **eyes and head should follow the cursor slowly and naturally**, with a slight delay and smooth acceleration and settling. Let her eyes lead slightly, followed by a smaller head turn. Avoid snapping, exaggerated rotations, or following every tiny mouse movement. Limit movement to comfortable anatomical angles, keep her torso stable, and gently return her gaze forward when the cursor leaves. Coordinate this with camera parallax so the movements do not exaggerate each other.

Every **7–10 seconds**, have her naturally extend the torch toward the camera, briefly pause, and return it. Coordinate her shoulder, elbow, wrist, and grip. Inspect the model's rig and facial controls first; use Blender if needed to prepare them.

Visible, realistic rain: Start rain when the 3D character appears. Create clearly visible rainfall at different depths, with natural gravity, slight wind, and torchlit highlights. Rain must visibly land on her rather than pass through her. Add small surface-aware splashes on her hood, shoulders, arms, and hand, with droplets collecting, sliding downward, and dripping from clothing edges.

Gradually darken and deepen the colors of fabric and fur **where rain lands**, and add subtle wet highlights to exposed skin. Keep sheltered areas beneath the hood comparatively dry. Use localized wetness masks, with damp fabric rather than plastic-like gloss. Add faint mist and ground splashes while keeping her face readable.

Animated torch fire: Attach realistic flickering flames to the torch tip, replacing or concealing any solid flame mesh. Include rising sparks, faint smoke, and warm dynamic light on her face, hand, and cloak. The fire must follow the torch precisely, respond subtly to wind and movement, and remain burning in the rain with occasional restrained steam effects.

Cursor parallax: Add noticeable, smoothly eased horizontal and vertical camera parallax, with weaker background movement. Keep angles controlled, prevent

exposed background edges, and leave text and navigation stable. Gradually enable parallax and gaze tracking after the reveal.

Use efficient Three.js/WebGL effects. Preserve existing narration and interactions, reset correctly on replay, and pause rendering offscreen. Test performance and clearly report any rigging or material limitations.
